FOREWORD

It is a truth universally acknowledged, that a plant in possession of a good and fortunate place in which to grow will reproduce: indeed it either reproduces or becomes extinct (with apologies to Harper 1990, Austen 2006, Dwyer 2016).

Globally, weeds are a significant problem.

They impact primary industries and biodiversity conservation (both terrestrial and aquatic), as well as communities, human health, infrastructure and culture.

Such global weed problems require a resource of equal magnitude to address them.

A Global Compendium of Weeds is such a resource.

No one denies that the word “weed” has always been an anthropocentric or human construct: it can simply mean ‘a plant that is out of place’. A generalisation follows from that construct, and it is one of the best pieces of evidence available to identify species that have a high risk of becoming weeds. Simply, plants “that have become weeds when introduced in one part of the world are likely to cause problems if introduced elsewhere” (Panetta 2002). This is the one of the reasons that this book is invaluable, it is a readily available resource to help those who need to predict the potential invasiveness of almost any species one can think of.

In this third edition, internationally acclaimed Rod Randall, a 32 year veteran weed research officer working with Western Australia’s Department of Agriculture and Food, has again extended his carefully constructed database of the worlds weeds to 4.8 million records. This database had initially doubled, and then has nearly doubled again, the number of records found in the first and second editions of this volume (Randall 2002, 2012), respectively. This, yet again, cements this book, and its author Rod, as one of the ultimate authorities on global weeds.

Every one of the 43,639 taxa listed in *A Global Compendium of Weeds* is a weed somewhere in the world. Once synonyms are accounted for, analysis of the 34,837 plant names shows both new and well known facts. For example, of the 539 plant families listed, the top three families by species are the Asteraceae, Poaceae and Fabaceae (Papilionaceae) – these accounting for well over 12,000 species. Surprisingly, four other families have well over 1,000 species each, that is the Rosaceae, Cyperaceae, Lamiaceae and Brassicaceae. Of the genera mentioned, the *Solanum* has 315 species while the *Carex*, *Euphorbia* and *Cyperus* genera also exceed 300 species.

Many in the ‘developed’ world have long sought out this reference as an accurate summary of global information and reference details on the ‘weedy’ status of any plant. This has informed weed risk assessment and management outcomes, policy and legislative decisions, as well as species specific management and research. What is less well understood is the

contribution that the book, released online since the second edition, has had in the ‘developing’ world. My PhD candidate Dorjee from Bhutan best summarises this:

“...your great contribution especially to a developing country with limited publications on weeds like Bhutan is immense. I have been your beneficiary throughout my PhD studies. I am now more than eager to contribute my inventory of alien plants in Bhutan to your database so that many more benefit from your selfless work.”

Human-mediated translocations of plants will continue to occur for a variety of purposes (e.g. Panetta 2002, Johnson 2012). In concert, and as custodians of nature, we need to continue to use alternate species instead of existing weedy ones, eradicate inappropriate introductions, contain valuable species that may also become weedy, and, as needed, reduce the impact of widespread weedy species and protect valued assets from their impacts (Auld and Johnson 2014).

In a world where national and international borders are less important than what is contained within them, and where weed management needs to carry on regardless, *A Global Compendium of Weeds* is a global resource for the weed problems we all increasingly share.

INTRODUCTION

Over many thousands of years plants have been a pivotal component in the development of numerous cultures and regions around the world. Within these cultures plants have facilitated the development of a huge range of occupations and created great wealth for millions of people. While these crops have created opportunities and driven economies other plants, and I have no wish to anthropomorphise here, have continuously undermined these agricultural efforts.

In a number of languages these species have been called weeds.

In the cut and thrust of ecosystems there are no weeds. The concept of a weed, while a human construct, does provide some measure of the value we place on the systems these plants appear in. Ecosystems have no concerns for the organisms that live, compete, eat, thrive and die within them, again that is a human issue. When humans place values on plants or animals that we consider are 'out of place' we need to acknowledge why.

For plants considered a weed of agriculture the concern is simple. Indeed the concept of an agricultural weed is as old as agriculture itself. These 'weeds' impact in a direct and measurable way on the production of any farmed species. They reduce potential yields, lower values through contamination, impede harvesting or other management activities. It matters not which agricultural system these 'weeds' grow in their impacts are easily recognised and measurable. Historically plants considered noxious or quarantine weeds were generally well known agricultural weeds.

The concept of the environmental weed is much younger and while its origin is debatable most would agree that the concept first garnered major recognition after Charles Elton's seminal 1958 publication on invasive plants and animals. Over the last few decades there has been widespread and increasing documentation of the world's environmental weeds. Subsequently many plants have been labeled environmental weeds and there are numerous lists and publications available. However unlike agricultural weeds it is much harder to define the impacts of most environmental weeds and there are far fewer species documented as environmental weeds compared to agricultural.

With numerous researchers working on this issue environmental weeds have never been higher on the international agenda but there is a long way to go before the potential and actual impacts of these plants are understood, documented and widely appreciated.

There are however several other categories applied to the plants listed in this publication. Some readers may wonder why I do not use the specialist terminology as is routinely used in some papers, terms such as ephemerophytes, agriophytes, archaeophytes or xenophytes* and there are more.

The answer is simple, this publication is not actually intended for use by readers who would ordinarily understand such terms. The original and continuing reason to publish this data is to assist people who work with, or are affected by plants, to make decisions about weedy or potentially weedy plants.

This publication is targeted at people who introduce, distribute, sell or grow plants, people who need to respond to reports of incursions or those who may generate the report. It should be used by farmers, pastoralists, home and hobbyist growers, production and retail nurseries, people involved with plants at any level of government and any and all volunteers who work with the environment and plants.

This is why the data is presented in Genus species order, rather than the more conventional Family, Genus species order. Once a user has determined the scientific name of their problematic plant it's a very simple matter to find its listing.

That some in academia may also find this publication useful is a gratifying bonus.

Finally, while there are many workable systems devised to determine if a plant could be a potential weed in a specific environment, the current simplest predictor is a species history. With many potential readers not having access to journal databases, the scientific literature or the expertise to use the literature and diagnostic systems that are available many decisions are made, or not, on poor or no data. That's why this publication is being freely distributed and it is my hope that others will also make it available as a free download, this is my permission to do so.

**Ephemerophytes*: non-naturalised, occasional immigrants, or waifs

Agriophytes: naturalised in natural and semi-natural habitats

Archaeophytes: plants that immigrated (into the region) before the end of the 15th century

Xenophytes: plants introduced unintentionally

THE DATA ANALYSIS

As this compendium is the last edition it was decided to include a basic analysis in the form of a number of charts, graphs, and comment of the data herein to provide readers with more greater background on the issue of global weeds.

THE ‘ORIGIN’ DATA

The origin of a plant was difficult to pull together in this publication. Any one species may have several hundred to over 1,000 references and many of these may list the origin, as determined by that publications author/s.

These origins may be very specific, listing individual countries or they may be rather general in nature listing continental groupings such as Europe, or Asia and they often vary considerably.

To avoid under reporting and at the risk of over reporting origins a set of eleven global regions were selected. The set of regions closely matches those reported in the compendium itself to maintain some consistency in approach. It also includes the ubiquitous reference of cosmopolitan or obscure. It is interesting to note the number of times this status is used by some publications where others will cite an origin.

The database was then queried many hundreds of times in its ‘Origin’ field for those countries falling within one of the eleven regions, subsequently adding to that regions origin count. There is undoubtedly an over reporting of species origins, but at the risk of countering the opinions of those who initially made such reports it was felt that provision of some data here is better than none, forewarned is forearmed (Graph. 1).

Graph 1: Number of species reported as originating from one or more of the 12 compendium regions. The total number of species reported with an origin is 15,176. The total number of referenced reports is 25,901.

THE ‘WEEDS OF’ DATA

Over the last 21 years a great deal of data was collected relating to weeds of various agricultural crops. Additionally many references also related to weeds of certain crops or cropping situations in general. A great many of the species in this compendium are considered agricultural weeds but not all of these reports specify the crop they impact on. To improve on this aspect where available the actual crops or agricultural scenarios impacted on are identified in this section.

Unsurprisingly the majority of weed reports come from the worlds major crops in the cereal groups which includes wheat, oats, barley, rice and other broadacre grains.

Weeds of pastures, plantation crops and fruits and vegetables make up the main reported groups (Graph. 2). This data is not definitive or complete, just indicative of the crops and agricultural situations many weeds are reported in.

Graph 2: Number of species reported as weeds of 18 various crops or cropping situations. The total number of species reported in this section is 6,229 with a total of 12,360 reports.

THE ‘DISPERSAL’ DATA

The database itself contains dispersal data for over 154,000 species however only data for those species documented in the compendium are provided.

When considering dispersal mechanisms this dataset considers the dispersal options and capabilities that plants employ to spread locally from an initial point establishment, be it an intentional introduction or unwanted incursion.

Humans are by far the most significant means of dispersal for a huge range of plant species, for a range of reasons, most often unintentionally (Graph. 3). The last value in the graph has been

truncated at 10,000 species to allow a better view of the bulk of the documented means of dispersal.

‘Livestock’ includes all those animals that fall into that general category and ‘Flyers’ includes bats as well as birds. ‘Escapee’ covers those species that are documented as escaping from cultivation from a point of intentional introduction by any means. Many species have multiple means of dispersal with 24,134 species reported in the compendium for a total of 44,261 species/dispersal combinations.

Graph 3: Means of dispersal reported for 24,134 species are reported, based on a total of 44,261 reports (last value truncated).

THE ‘PATHWAYS’ DATA

Pathways are important to understand when developing and implementing surveillance and/or management plans. An understanding of the pathways plants use to access regions beyond the reach of their natural dispersal mechanisms is critical data (Graph. 3).

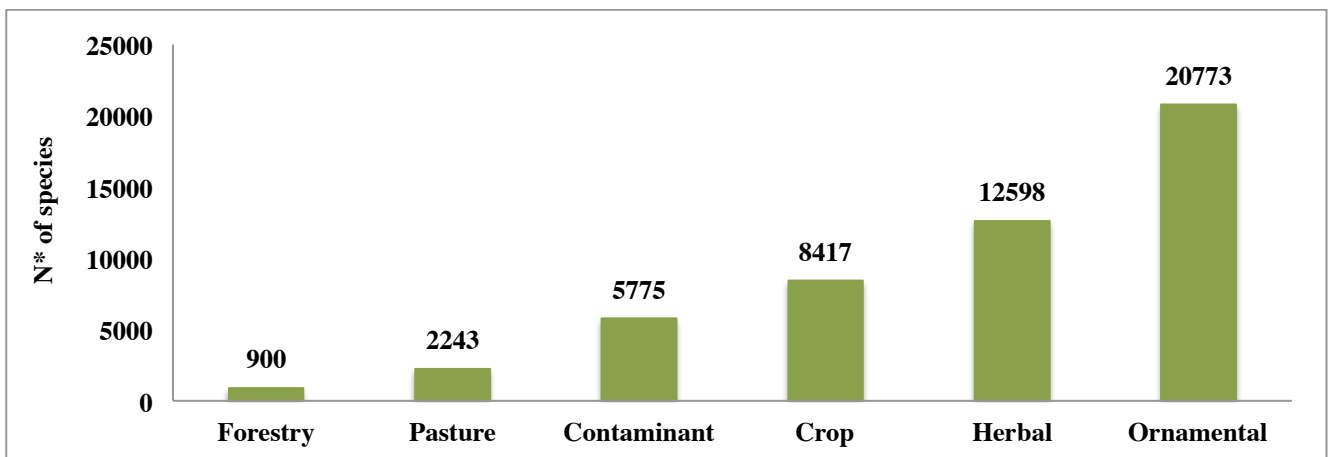

Pathways are therefore the means by which plants can enter new regions or territories and inevitably these pathways are human mediated and controlled.

Biosecurity and Quarantine agencies routinely document species pathways and this is critical data in the development of quarantine import conditions and subsequent market access provisions. Some of the pathways reported here are cumulative in nature. The pathway ‘Crop’ for example covers all crops that are known to provide a pathway for the species reported, often as a contaminant in the crop itself. The same caveat applies to

‘Forestry’ and ‘Pastures’. Some references however only indicate a species is a contaminant, without being any more specific but may include machinery, vehicles and certain bulk products as well as bulk seed.

The global trade in ornamental plants is still by far the most expansive pathway with over 20,000 species traded globally. This number is almost certainly a very conservative estimate as the database has not striven to collect lists of all available species. Furthermore there is an appalling lack of taxonomic accuracy/awareness in the global plant supply industry making it very difficult to validate many names used.

Interestingly the global trade in herbs, or medicinal plants, is burgeoning and, while not as large as the ornamental trade, does involve significant numbers and does contain many weedy plants. Most herbal species are also considered ornamentals further improving a species chances of entering new territory.

Graph 3: Pathways reported for 26,541 species, with a total of 50,706 pathway/species combinations.

THE ‘STATUS CODE’ DATA

The data in this section is presented in two ways. The total number of reports per status code, which is the cumulative count of all references for every species for each status code (Graph 4) and the total number of species for each status code (Graph 5).

‘Naturalised’ is clearly the largest and most significant status recorded with most number of reports and the largest number of species. This is almost certainly because much of the effort in documenting references for the database has focussed on looking for flora lists which involve large numbers of species.

Much of the published weed literature are articles on common agricultural weeds, usually discussing a half dozen or less

species. Rather than try to collect every single weed related article there is a greater reward in looking for larger species lists when compiling this sort of data. Flora lists, with indicated naturalised flora or papers documenting the weeds of specific situations or regions are therefore of paramount value.

One significant disappointment when searching for data is the relatively common practise of authors compiling large flora lists then analysing those lists and presenting the analysis results without providing the actual list itself. It often eludes many authors that the species makeup of such lists is as important, if not more so, than the analysis results. For the same reason this document would be worth very little if just these few summary graphs were published, interesting but essentially useless.

Graph 5: Total number of species for each status code.

GLOBAL WEED NUMBERS

Table 1. provides a country by country breakdown of the numbers of documented weeds and the number of references that provided those names. Maps 1 and 2 display this data differently. The reported numbers by country (Map 1.) and by distribution classes as a form of ‘heat map’ of the reported global weed flora by the

same countries (Map 2.). The third world map (Map 3.) shows the reported numbers of weeds and naturalised plants for each compendium region. The records from references listed as ‘Global’ have been included in this map with the countries those sub-references relate to listed in Appendix One.

NUMBERS OF REFERENCES AND SPECIES

At a most simplistic level some may form a view of a plant merely by considering the number of references listed against it's name. The simple interpretation being the greater the number of references the worse the weed.

In the first compendium this would have been difficult with only 300 references to rank the distribution of reference counts. The second edition had over four times that number and this edition, has more than seven times as many references as the first edition.

With 2,015 references representing 35,252 currently accepted names, plus the associated 8,892 synonyms, this edition contains a combined total of 443,089 bibliographically reported records.

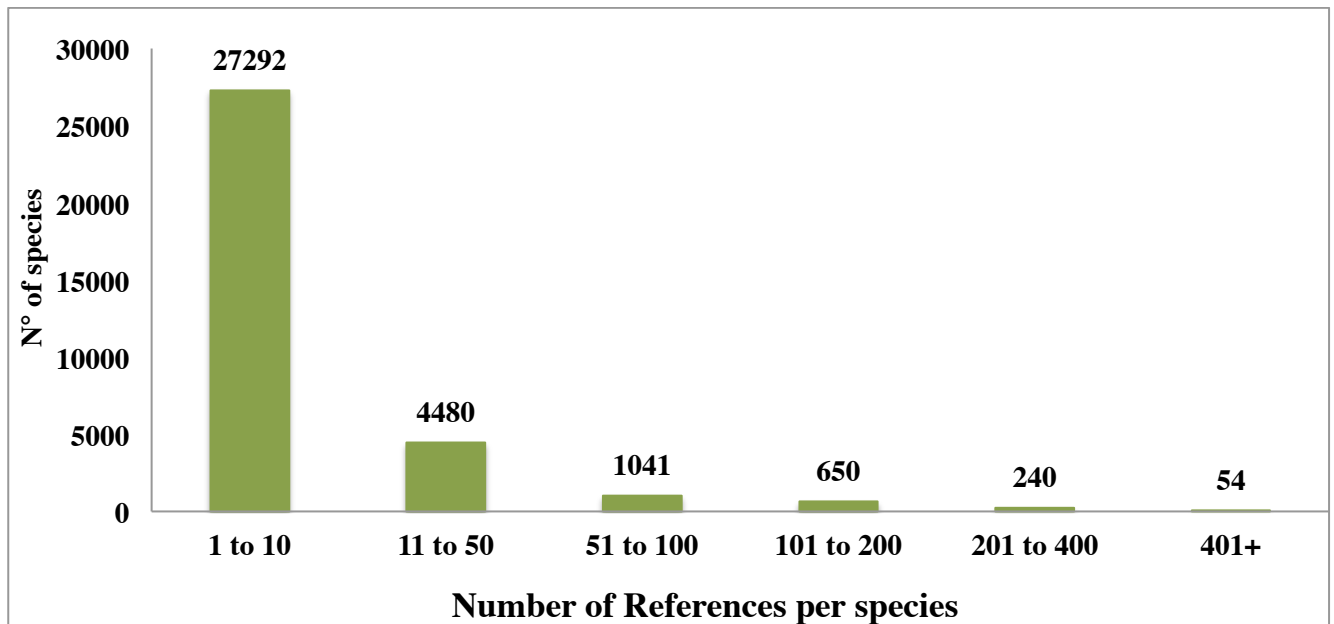

The class groupings selected below clearly illustrate that well over half of all reported weeds have ten or fewer references in this edition (Graph 6). 27,292 species represents the '1 to 10' reference group, 80.8% of the compendiums content.

Taxa numbers in each class drops significantly as the number of references represented increases. The largest group, representing '401 or more' references, contains only 54 species or 0.13% of the compendium.

If the '1 to 10' references group is separated into individual reference score classes the same pattern repeats, a rapid drop off in species numbers as the number of references increases (Graph 7.).

It would certainly be presumptive to state that any species with a low reference count would not be a significant weed. However it is clear that the higher referencing classes do contain the world's most important weed species.

While newly significant weeds may yet emerge from these poorly referenced species no-one should be surprised by the widely and heavily reported species listed within.

GRAPH 6: Number of species (above each column) within each of six weed reference number groupings (accepted names only)

GRAPH 7: Number of species (above each column) within each weed reference number group with class '1 to 10' above expanded. Note: Classes 11 to 50 and higher are identical to Graph 6 above.

THE 'GLOBAL RISK SCORE'

A new inclusion in this edition is a scoring system that calculates a plants risk potential as a ranking that can be compared to other weed species. The system was originally presented at the 20th Australasian Weeds Conference in Perth, Western Australia in September 2016.

The full paper (Randall, 2016) and its associated dataset is available to download at Research Gate, therefore only a short summary will be presented here.

Rather than relying on a number of biological or ecological traits this system considers the outcomes of a plant species' interaction with humans and its observed/reported behaviour around the world.

This approach is supported in part by a number of studies that concluded that the single most useful characteristic of a plant in predicting weediness is its behaviour as a 'Weed Elsewhere' (Gordon *et al.* 2008, Daehler and Carino 2000, Daehler *et al.* 2004, Mack 1996, Parker *et al.* 2007, Rejmánek *et al.* 2005).

The 'Weed Elsewhere' question in many WRA systems is not a function of a plant's biology or ecology but rather how a species' behaviour is perceived by humans. Consequently a

number of the database characteristics used in this study were drawn from attributes that are closely allied to human behaviours, observations and values. This includes categories like 'intentionally grown' or 'considered to have medicinal values' and other categories of human values where these plants interact and impact, their uses and how they are dispersed by people.

A species introduction into a new region can be broken down into three basic phases: Entry, Dispersal and Impact

Subsequently the content of fourteen database fields were selected and allocated against the appropriate phase (Table 2). Each category was then given a Value (last col) and a weed risk score was calculated using the following function:

$$\text{WEED RISK SCORE} = \text{ENTRY (A + B + C + D + E)} \times \text{DISPERSAL (F + G + H + I + J)} \times \text{IMPACT (K + L + M + N)}$$

The paper also outlines how a species risk ranking may be calculated manually so access to the database is not essential.

The scores and the global risk rankings for 5,018 species are provided here.

OVERALL DATA SUMMARY

Table three provides a broad summary of the total numbers of records, species, countries and the highest reported plant families and genera.

Graphs eight to eleven clearly illustrate that the bulk of the world's weedy flora is dominated by a relatively small number of families and genera. None of these families or genera provide any real surprises, as shown by any large group of species there is huge variety, variation and many more species within that have not been reported as weeds.

The one large family that does not live up to a potential its size may suggest is Orchidaceae. As the 40th ranked family, with 235 reported taxa, it is a long way from the 5,094 taxa in Asteraceae, 4,807 in Poaceae and a combined total of 3,572 for the Fabaceae the top three families. Orchids are generally not considered weedy but do get reported behaving as weeds for a range of reasons even including the ubiquitous vanilla orchid (*Vanilla planifolia* Jacks.).

The sharp drop in reported numbers of taxa per family (Graph 9) is mirrored by the genera (Graph 11) in a similar manner to the reference number relationship illustrated by Graphs 6 and 7.

This edition of the compendium cites from 2,112 references reporting 43,639 taxa, covering 298 countries, altogether representing 432,042 database records. These records were drawn from a significantly larger dataset comprising over 1.2 million plant names referentially linked to 4.8 million bibliographically referenced reports from many thousands of sources.

UNDERSTANDING EACH RECORDS INFORMATION

Each compendium record can be comprised of up to 18 components, each are explained below.

Genus Species and Author The taxonomy of weeds is very fragmented and many sources used old names. Rather than update these old names they have been left as published by the source author and linkages indicated between records that are synonyms and those that are the current name. While all effort has been made to determine the appropriate links between related records, it is possible some may have been overlooked or never determined. With the large number of sources used to determine synonymy it was common to encounter differences of opinion as to the correct name and a decision, right or wrong, had to be made.

Plant FAMILY Again, decisions right or wrong, had to be made.

Synonyms Are only listed when they are referred to elsewhere in the compendium. Listed alternate names will refer to the current name and the current name will refer to all listed alternate names and provide a reference count for each of those names. This removes the need for a scientific name index.

There may be some duplication of names due to minor spelling variations that have been overlooked. Whilst all effort has been made to remove these some may remain. If any duplicate names are detected please inform the author.

Hybrids, the parents are listed where known

Common Names Are not listed in this compendium. They create to much confusion amongst readers not aware of the correct scientific name they are looking for and take up a great deal of room in the listings. Overall they add little value to the compendium. Common names would also require an extensive index listing which is not needed in this format where all the alternate scientific names are internally referenced.

USAGE COMMENTS

The number after each section represents the number of species in the compendium with this status (first number this edition, second number previous edition). The number in brackets after classifications in the following commentary are the number of species in this compendium that meet the stated criteria.

Total n° of refs: The total number of references for this species, including all synonyms and accepted names. This number appears on all related records.

Global Risk Score: The global weed risk score as per the 2016 publication by Randall and available here: https://www.researchgate.net/publication/307638532_Can_a_plant%27s_cultural_status_and_weed_history_provide_a_generalised_weed_risk_score (5,081)

Rating: As above

Toxic: Where a species is documented as toxic. The level of toxicity or parts considered most toxic are often difficult to determine, as sources rarely indicate this. These factors and the varying susceptibility of different species from humans to livestock to wildlife should all be considered. (3,310)

Aqua: The use of "aqua" indicates a species capacity to survive under very wet conditions from free floating herbs to trees or shrubs that can survive saturated or inundated soils.

Habit: A simplified form of a plants longevity and basic form.

Preferred Climate: Derived from the database and any countries where the species is associated with these four basic climates: **Dryland, Mediterranean, Tropical** and **Subtropical**

Origin: A species origin can often be difficult to determine accurately and sources will often conflict with one another. The approach in this publication is to combine all the cited origins as

they relate to 11 major regions plus 'obscure' or 'cosmopolitan'. While not accurate enough for some it's the best outcome possible from so many varying sources. In determining the origin many hundreds of searches were conducted for all possible combinations of origin as referenced in the origin field of the database. A total of 15,176 species have an origin reported.

The reported regions are:

1. **Africa**
2. **Aust** – Australia
3. **C Am** - Central America (Guatemala to Panama and the Caribbean)
4. **C Asia** - Central Asia (Sri Lanka to Kazakhstan and Turkmenistan to Bangladesh)
5. **E Asia** – Eastern Asia (China and Korea to Thailand and Japan)
6. **Europe** (Ireland to Russia and south to Bulgaria and Greece)
7. **NZ** - New Zealand
8. **N Am** - North America (Mexico to Iceland)
9. **S Am** - South America (south from Colombia)
10. **SE Asia** - southeast Asia (Malaysia to Philippines and Papua)
11. **W Asia** - western Asia (Georgia to Yemen and Turkey to Iran).

Major Pathways: Mentioned here are the five major intentional and one accidental pathway by which the vast majority of plants are distributed globally: These major pathways are:

Contaminants: accidental contaminants in produce, seed, livestock, possessions, vehicles or equipment (5,775)

Pastures: species used in pasture and forage production (2,243)

Forestry: species used in forestry projects including timber, firewood, charcoal and other perennial tree related industries (900)

Herbal: a vast range of species used as herbal medicines, natural therapies and other related uses (12,598)

Crops: covering all major crops and a great many minor crops where the species is known be either intentionally cultivated or harvested for human or animal consumption or other utility purposes (8,417)

Ornamental: the largest range of plant species and often including multipurpose plants with numerous uses (20,773)

Dispersed by: The major dispersal mechanisms from the database are mentioned here:

Humans: intentional dispersal for any number of reasons although the vast majority are for ornamental use (22,804)

Vehicles: a well documented means of dispersing many plant species as a contaminant on and in a range of vehicles and other mobile machinery (993)

Animals: sources not specific but can include native species as well as livestock (3,752)

Livestock: where sources mention livestock or domestic animals (2,574). This includes records for Cattle (721), Donkeys (105), Goats (65), Horses (378) and Sheep (1,880).

Flying animals: species documented dispersed by birds and bats (739)

Water: (3,136) and **Wind:** (1,210)

Escapees: includes all those plant species that are known to escape cultivation into the surrounding country (5,904).

Seed Longevity: While there are only a relatively small number of records with data reported in this field (1,531) it is very valuable information. The four possible outputs are listed and explained below. All data used here was drawn from the LEDA seed trait database (Kleyer *et al.*, 2008). The LEDA trait standards for seed longevity are an excellent resource.

Present: a seed bank has been demonstrated to be found in the soil but no time frame on longevity is given (175)

Transient: species with seeds that persist in the soil for less than one year, often much less (476)

Short term: species with seeds that persist in the soil for at least one year, but less than five years (310)

Long Term: species with seeds that persist in the soil for at least five years (570)

Weed of: Listed here are those impacted crops or industries specifically reported in the database. As previously mentioned this data is not definitive or complete, just indicative of the crops and agricultural situations many weeds are reported in.

COUNTRY OR REGION: Each cited reference begins with the country or region as stated by that reference. Some very large sources contained lists of species for many countries. When possible these lists have been reproduced for every country hence the same reference code can appear with a different country. Records for common weeds can then, with the same reference code, appear numerous times with different country names while the reference itself is listed as 'Global'.

Some references are still cited as 'Global' but do not break down into specific countries. This is where the actual countries involved are not specifically cited or the country attribution was not feasible from that source.

STATUS CODES: A group of relatively standard descriptors were used to form the status field of the dataset. In this edition the status code is again listed after each reference source code so readers can be certain of a species status as defined by each individual reference. This edition also lists the country which that reference applies to, hopefully reducing the need to continually consult the reference list.

The numbers cited at the end of the following sections relates to the numbers of species meeting each sections criteria in this edition (first number) and the last (2nd) edition (last number).

A - Agricultural Weed Species commonly found in or impacts on any harvested or farmed commodity such as broadacre crops, plantations, orchards, small vegetable plots etc. (16,968 - 10,107)

C - Cultivation Escape Species may have escaped from gardens, cultivation or both; source not specific but includes some crop and pasture species. (4,858 - 4,463)

E - Environmental Weed Species that invade and impact on native ecosystems. (5,688 - 4,980)

D - Dispersed by Species with this code have details on their dispersal mechanism in the cited reference (9,619 - NA)

G - Garden Escape Garden species known to have escaped, either directly by seed or other propagules moving out of the garden, or indirectly by establishing from dumped garden waste. Other garden escapes originate from abandoned gardens, graveyards and commercial waste disposal sites, to name just a few. (5,709 - 3,072)

I - Invasive Species may have escaped from gardens, cultivation or both; source not specific but includes some crop and pasture species. (6,331 - 4,186)

N - Naturalised Species has self-sustaining and spreading populations with no human assistance, but does not necessarily impact upon the environment. A species' capacity to naturalise in foreign environments, however, is a good

indicator of its weed potential. The letters 'nC' means that naturalisation has not been confirmed. (22,588 - 18,048)

Q - Quarantine Weed Species prohibited entry under a countries quarantine laws, either because it's not present or present and under a management program. (3,039 - 1,818)

R - Ruderal Species listed as ruderal in the database references where a species is considered to have a strong association with human disturbance and regularly disturbed habitats (3,583 - NA)

U - Casual Alien These species appear with no direct (apparent) human assistance, survive, possibly set seed, but do not persist. They then may appear again some seasons later, but do not develop persistent populations. Such species are often considered as ruderal species but for this publications purpose the association with human disturbance is not a requirement (9,074 - 7,002)

W - Weed Most common term used. These plants are nearly always economic weeds (i.e., pests of agriculture, horticulture, turf, nurseries etc.). However when a source is not conclusive in this area then 'weed' is used. (20,630 - 17,882)

X - Noxious Weed Species that landholders are required by an act of law to manage, control or eradicate. For some countries this term also encompasses quarantine species (i.e., US Federal Noxious Weeds). (2,175 - 1,595)

Z - Contaminant Species that have been documented as a contaminant, usually as seed but potentially as other viable plant parts in a variety of products and pathways. (4,871 - 3,283)

REFERENCE SOURCE CODES

Numerical codes for references used in the Compendium (see reference table for full details).

For a visual key to reading and dissecting each record turn to the next page titled "READING A RECORD".

NOMENCLATURE AND ERRORS

Every attempt has been made to retain the original species names as supplied by the authors in each source. At times, where there have been spelling errors, some records have been changed and more than likely, but hopefully not too frequently, errors may have been made at this end of the data daisy chain. Some spelling errors or variations may not have been detected in the screening process when adding new data sources. For these and any other errors the author takes full responsibility. It would be appreciated if reader's finding errors could advise the author.

DATA SOURCES

For most published books and articles the conventional citation is usually sufficient, but where it would assist the reader any other appropriate information has been included. There are numerous personal communication sources, these will provide as much information and background as necessary to validate the credentials of the source.

READING A RECORD

1. Genus species and author citation
2. The Family as determined for this publication
3. Any alternate names listed in this compendium with the number of references for that record in brackets.
4. Total number of references for the accepted name and all its listed synonyms.
9. Any known major pathways
10. Known major modes of dispersal

12. If record is a synonym the accepted name is indicated here

13. The reference total here is only the sum of this record and the references attributed only to the accepted name. It does not include other cited synonyms in this work. These are all summed in the accepted name record.

ACKNOWLEDGMENTS

Over the twenty plus years of the development of this database a great many people have directly or indirectly had significant input into its content and construction.

It would be far too difficult now to even attempt to list all those who have helped over that time. Needless to say it's a long list and the best I can do here is to thank one and all for their most generous help, input, comments, advice and efforts over many years.

Here's hoping the mother dataset that provided so much will continue to grow in the years to come, albeit under someone else's guidance. That fact that this database even exists is more serendipitous than many may suspect.
